Kisan Mitra — Crop Doctor Report

Report ID: KM-000003

Date: 2026-10-31T23:10:45

Crop: Unknown (likely a broadleaf ornamental or vegetable)

Possible condition: Suspected fungal leaf spot or blight (e.g., Septoria, Anthracnose, or Phytophthora)

AI assessment (not a calibrated probability): 45.00%

Severity: Moderate to High

Visible symptoms

- Large, irregular brown to black necrotic lesions
- Distinct yellow halos surrounding the dark spots
- Leaf tissue collapse and drying
- Lesions appearing on both upper and lower leaf surfaces

Suggested treatment / care

- Remove and destroy all affected leaves to reduce inoculum
- Apply a broad-spectrum fungicide labeled for the specific crop and pathogen
- Improve air circulation around the plant canopy
- Consult a local agricultural extension service for a definitive diagnosis

Prevention

- Avoid overhead watering to keep foliage dry
- Ensure proper plant spacing for airflow
- Rotate crops if this is a recurring issue

- Apply mulch to prevent soil-borne pathogens from splashing onto leaves

Important: This is an AI-generated assessment based on visual symptoms. The specific pathogen cannot be confirmed without laboratory testing. Do not apply pesticides without a confirmed diagnosis from a local agricultural expert.

This is an AI-assisted image assessment, not a laboratory diagnosis. Image-only identification can be wrong. Confirm serious cases with a local agricultural expert. Follow locally approved product labels; no pesticide dosage is prescribed here.
